Executive Summary

The Occupational Information Network (O*NET) is a comprehensive system for collecting, organizing, describing, and disseminating information on occupational requirements, work requirements, and worker attributes. The O*NET database is designed to be the most comprehensive standard source of occupational and skill information in the United States, providing valid, reliable, and current data for all users.

O*NET data are collected primarily through the Establishment Method, which draws from a sample of establishments, and workers within those establishments. Each participating worker is asked to complete one of four randomly assigned survey questionnaires: Skills, Knowledge (including Education and Training, and Work Styles), Generalized Work Activities, and Work Context. Workers also complete a basic demographic questionnaire and a brief, occupation-specific task inventory.

This report investigates the possible extent of nonresponse in estimates from the O*NET Program. Nonresponse bias is the expected difference between an estimate from the responding cases and an estimate from all cases originally selected from the target population. Three types of nonresponse are examined in this report: establishment nonresponse, employee nonresponse, and item nonresponse. These three types of nonresponse can lead to biased inferences if nonresponse rates are high and respondents and nonrespondents differ relative to the requirements of interest.

An examination of both establishment and employee response rates found that nonresponse patterns are somewhat related to essentially all variables considered in the analyses. However, when examining the distribution of respondents and nonrespondents across various frame attributes, it was found that the overall potential for nonresponse bias at both the establishment and the employee levels was negligible. For both establishments and employees, both the absolute size of any potential bias and the effect size were found to be small for all variables considered. Because nonresponse patterns for both establishments and employees are related to the substantive variables measured in the study, using these variables for nonresponse adjustments to the analysis weights should be effective in reducing the minimal effects, if any, due to nonresponse bias in the analysis.

At the item level, it was found that response rates varied across questionnaire types and questions. In most cases, the response rates were extremely high. This finding held at the establishment and employee levels—that is, the potential for significant nonresponse bias due to item nonresponse is negligible.

1. Introduction

Effective December 1, 1997, RTI International contracted with the National Center for O*NET Development to provide sampling, data collection, data processing, and data analysis services for the O*NET Data Collection Program. On July 26, 2002, the U.S. Department of Labor submitted to OMB a request for an extension of approval for the O*NET Data Collection Program (OMB control number 1205-0421). On September 25, we received approval of this request for a 3-year extension, subject to several terms. As one of those terms, a nonresponse analysis was conducted on data from the first three analysis cycles. This report documents the results of that analysis.

The Occupational Information Network (O*NET) is a comprehensive system for collecting, organizing, describing, and disseminating information on occupational requirements and worker attributes. The O*NET database is designed to be the most comprehensive standard source of occupational and skill information in the United States.

The National Center for O*NET Development (Center) provides core staff with acknowledged expertise in the areas of occupational analysis and assessment research and development. The Center manages projects and contracts and provides technical support and customer service to users of O*NET data and related products.

The O*NET Data Collection Program is a cooperative effort involving several organizations. Under the overall direction of the Center, RTI is responsible for data collection, data processing, data cleaning, and some of the data analyses. The Human Resources Research Organization (HumRRO) and North Carolina State University also conduct data analyses for the Center, and MCNC, Inc. is responsible for publication of the data.

The O*NET Data Collection Program is an ongoing effort to populate and maintain the O*NET database with valid, reliable, and current occupation and skills data. O*NET data are used by a wide range of audiences, including individuals making career decisions, the public workforce investment system and schools making training investment decisions, educational institutions preparing the future workforce, and employers making staffing, economic development, and training decisions. The O*NET program provides a common language and framework to meet the needs of various federal programs, including workforce investment and training programs of the Departments of Labor (DOL) and Education (ED). The O*NET database and companion O*NET Career Exploration Tools are used by many private companies and public organizations to develop applications tailored to meet their needs and the needs of their customers. Further information about the O*NET program can be found at the National Center for O*NET Development's Web site, www.onetcenter.org, and at the U.S. Department of Labor, Employment and Training Administration's Web site, www.doleta.gov/programs/onet.

The primary method for collecting this information is the Establishment method, a survey of establishments and workers within those establishments. This is a two-stage design that uses (1) a statistical sample of establishments expected to employ workers in each specific occupation and (2) a sample of workers in the occupations within each sampled establishment. The sampled workers are asked to complete the survey questionnaires.

Four domain questionnaires are used to collect data from sampled workers: Skills, Knowledge (including Education and Training, and Work Styles), Generalized Work Activities,

and Work Context. Sampled workers are asked to complete one randomly assigned domain questionnaire, a basic demographic questionnaire, and a brief, occupation-specific task inventory. Workers may either complete the paper questionnaire and return it via mail or complete an online questionnaire at the project Web site.

Data collection operations for the main study began in June 2001 and are ongoing, with analysis activities conducted in overlapping cycles. This report analyzes the combined response experience of the first three analysis cycles. Data collection was completed for each analysis cycle on the following dates:

- Analysis Cycle 1: July 2002
- Analysis Cycle 2: July 2003
- Analysis Cycle 3: December 2003.

This report analyzes the combined response experience of the first three analysis cycles. **Section 2** of this report describes the sampling phases and data collection activities relevant to the response process for the O*NET Data Collection Program. **Section 3** discusses how nonresponse can lead to biased estimates. **Sections 4, 5, and 6** present the findings concerning establishment, employee, and item nonresponse, respectively. Conclusions are presented in **Section 7**.

2. Summary of Sample Design and Data Collection Methods

The primary source of information for the O*NET database is a survey of establishments and sampled workers from within selected establishments. This survey is referred to as *Establishment method* data collection. Under this approach, incumbents were sampled in their workplaces using a two-stage sample design, with establishments selected in the primary stage and employees in the secondary stage.

For sampling and data collection purposes, occupations were grouped into waves of approximately 50 occupations each. The waves were designed to contain occupations that may be found in similar industries. A primary stage sample of establishments was selected from lists supplied by either InfoUSA or Dun & Bradstreet (D&B).¹ These establishments were selected from industries expected to employ the occupations. Up to 10 occupations were then randomly assigned to each establishment for possible data collection.

The sample of establishments for each wave was fielded in four sub-waves. The sub-waves are identified as *X.1*, *X.2*, *X.3*, and *X.4*, where X represents the set of primary occupations and the number following represents the order in which the sub-waves occur. In this case, *X.1* is the first sub-wave and *X.4* is the last.

Each sub-wave sample consisted of a different number of occupations and establishments. All occupations were included within the first sub-wave, *X.1*. Experience gained from the first sub-waves was used to more effectively target the sample to industries and establishments where the occupations could be found. This process of gaining experience from the previous wave occurred for each subsequent sub-wave. Any occupation that required additional respondents was included in the next sub-wave.

The selected establishments were contacted using the 13-step process shown in *Exhibit 1*. RTI maintained a staff of Business Liaisons (BLs) who contacted the establishments and completed these process steps. Steps 1 through 5 have the most relevance to understanding the analyses in this report and are described below.

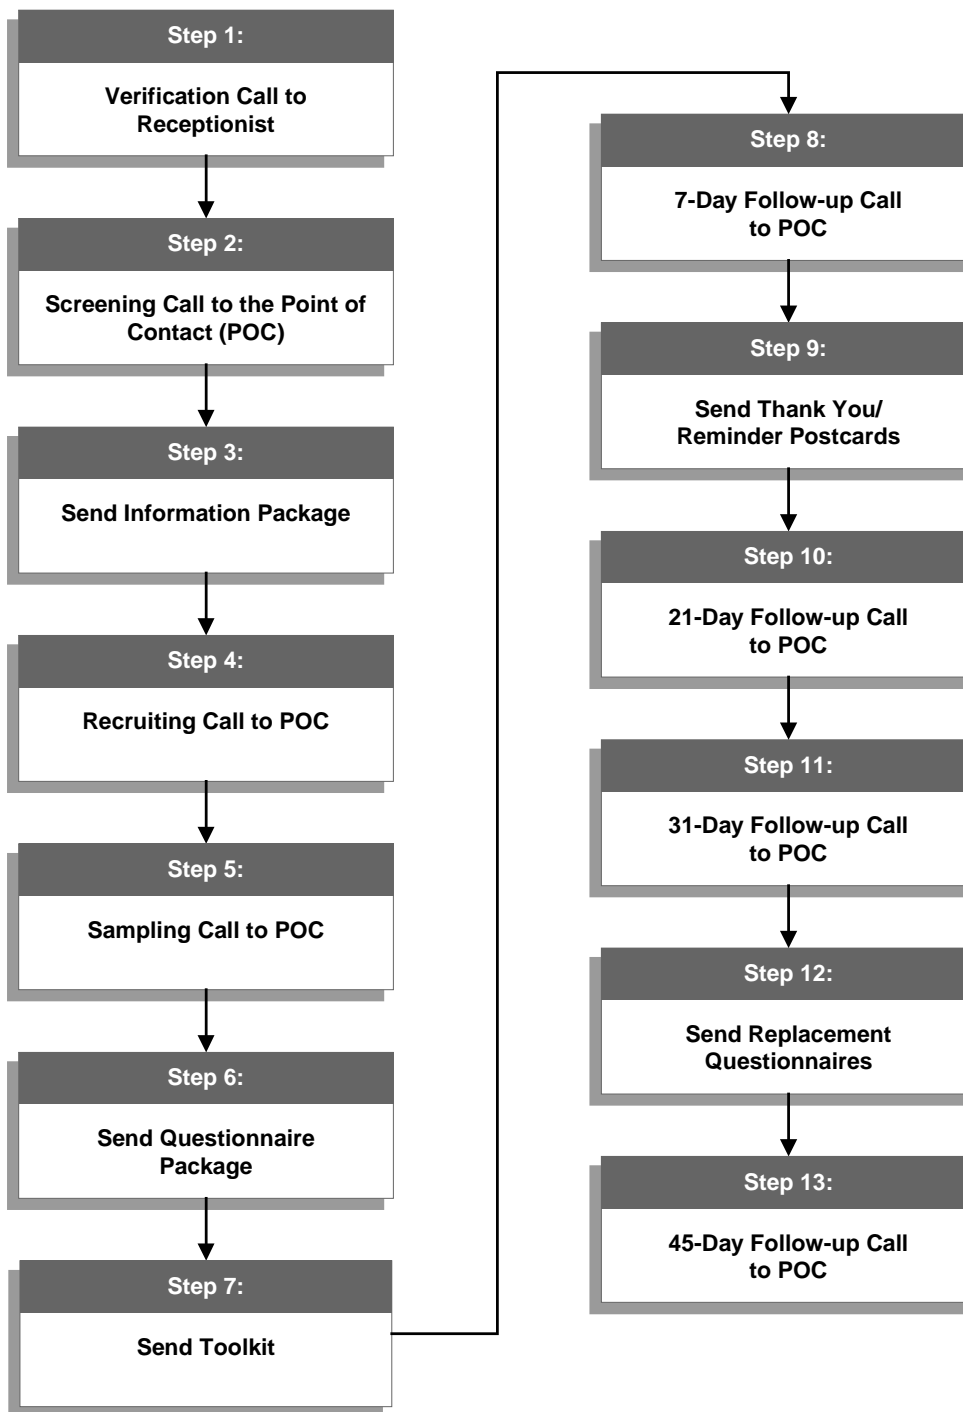

Step 1. Verification call to receptionist: The BLs conducted an initial call to each establishment to determine if the establishment was the one selected from the D&B list and whether the business was still in operation at the expected address. The BL also obtained contact information for a possible point of contact (POC).

Step 2. Screening call to the POC: A screening call was conducted with the POC to confirm that the BL had the correct POC and to determine if the establishment likely employed any of the occupations assigned to the establishment.

Step 3. Send information package: The POC was mailed an information package with information about the study and a more detailed description of the occupations assigned to the establishment.

¹ Waves sampled prior to October 2003 used the InfoUSA list, and all subsequent waves used the Dun & Bradstreet list.

Exhibit 1. Establishment Method Data Collection Flowchart

Step 4. Recruiting call to POC: During the recruiting call, the BL:

- verified that the information package had been received;
- confirmed that the POC was qualified to serve in the POC role;
- reviewed with the POC the occupation descriptions for the target occupations to determine whether the establishment had any employees in those occupations.

If one or more target occupations were present, the BL

- explained the O*NET program in greater detail, answered questions, and attempted to secure the POC's commitment to participate;
- explained to the participating POC the need to prepare a numbered roster of employees for each identified occupation, for use in selecting a sample of employees;
- set an appointment for the sampling call, allowing sufficient time for the POC to compile the occupation rosters.

Step 5: Sampling call to the POC: During this call, the BL obtained from the POC the number of names on each occupation's roster, and a sample was selected using a preprogrammed random sampling algorithm. The BL then informed the POC which employees were selected for each occupation. The POC was asked to note the line numbers of the selected employees on his/her list(s) so that the POC would know who was in the employee sample.

In subsequent steps, the questionnaires were mailed to the POC for distribution to the selected employees and follow-up calls were made to the POC to prompt for employee response.

Three types of nonresponse are examined in this report: establishment nonresponse, employee nonresponse, and item nonresponse. Nonresponse from the establishment can occur at Verification (Step 1), Screening (Step 2), Recruiting (Step 4), or Sampling (Step 5). For simplicity, in subsequent sections of this report, nonresponse at any of these steps is called *establishment nonresponse*. Another type of nonresponse occurs at the employee level when a selected employee fails to complete and return a questionnaire. This is called *employee nonresponse*. Finally, employees who return their questionnaires may inadvertently or intentionally skip one or more items on the questionnaire. This type of missing data is known as *item nonresponse*. The remaining sections of this report discuss the observed levels of these three types of nonresponse over the first 3 analysis cycles.

3. How Nonresponse Is Related to Bias

Nonresponse bias is the expected difference between an estimate from the responding cases and an estimate from all cases originally selected from the target population. The extent to which nonresponse bias occurs ultimately depends on (1) the extent of missing data and (2) the difference in an estimate between respondents and nonrespondents. For example, consider the following equation:

$$\bar{X} = p_R \bar{X}_R + p_N \bar{X}_N, \quad (3.1)$$

which says that an overall population estimate, \bar{X} , depends on the proportion of respondents and nonrespondents (denoted p_R and p_N , respectively, with $p_R + p_N = 1$) and the mean response from both respondents and nonrespondents (denoted \bar{X}_R and \bar{X}_N). Bias in an estimate due to nonresponse is given by the following equation:

$$\text{Bias}(\bar{X}_R) = \bar{X}_R - \bar{X}, \quad (3.2)$$

demonstrating that bias varies as a function of the overall population estimate and the mean response from respondents. The bias of an estimate due to nonresponse increases as the difference between \bar{X}_R and \bar{X} increases. Now, substituting equation 3.1 into equation 3.2 gives

$$\text{Bias}(\bar{X}_R) = \bar{X}_R(1 - p_R) - p_N \bar{X}_N, \quad (3.3)$$

and since $1 - p_R = p_N$, equation 3.3 can be expressed as

$$\text{Bias}(\bar{X}_R) = p_N (\bar{X}_R - \bar{X}_N). \quad (3.4)$$

Equation 3.4 reveals that the components of nonresponse bias depend upon the proportion of nonrespondents and the distance between mean responses for respondents and nonrespondents. If both components are small, then the bias should be negligible. For bias to be important, a large proportion of nonrespondents (p_N) should exist with a large difference between the mean responses (Kish, 1965). When using sample data to approximate bias, the components p_N , \bar{X}_R , and \bar{X}_N can be estimated with sample data across attributes that can be measured for both respondents and nonrespondents. It is rarely possible to measure any of the primary study outcome variables on the nonrespondents, or they would be respondents. Thus, it is necessary to turn to other variables that are available for both respondents and nonrespondents to serve as surrogates for the primary outcome variables. If respondent data indicate that the surrogate variables are related to the primary outcome variables, then any nonresponse bias, or lack thereof, observed in the surrogate variables can be inferred to the primary outcome variables. Such approximations are not deterministic but can give evidence of potential nonresponse bias.

The likelihood of missing data may be related to an observed variable, such as establishment size. For example, employees from larger establishments may be less likely to respond than employees from smaller establishments. Analyzing skills across jobs within an occupation could therefore be subject to bias if the work performed differs systematically by establishment size—that is, if employees from larger establishments tend to respond differently from employees from smaller establishments. This is evident when noting that both components of nonresponse bias (p_N and $\bar{X}_R - \bar{X}_N$) would be magnified in this hypothetical example because (1) employees in larger establishments may be less likely to respond and (2) if they do respond, they may respond differently from employees in smaller establishments.

In general, restricting an analysis to only those cases that are observed may introduce bias into the results unless the missing data mechanism is accounted for in the analysis (Graham, Hofer, & Piccinin, 1994; Little & Rubin, 1987; Schafer, 2000). Weighting is one common method of adjusting for nonresponse patterns based on observed values (Little & Rubin). The O*NET Data Collection Program incorporates weighting as one method to protect against the influence of nonresponse bias.

To reduce potential bias on the estimates caused by unit nonresponse, an adjustment is applied to the sampling weights at both the establishment and the employee levels. Unit nonresponse adjustments are computed using a response propensity modeling approach described in Folsom and Singh (2000). The Folsom and Singh modeling approach is a generalization of constrained logistic models first suggested by Deville & Särndal (1992). This approach is used to adjust for nonresponse because it has been shown to be more effective at correcting for nonresponse bias than the more commonly used weighting class approach. The increase in effectiveness comes from the ability to incorporate a greater number of correlates of nonresponse in the modeling approach than would be possible with traditional weighting class methods. This is particularly important for the O*NET survey because the respondent sample sizes within an occupation are typically small, with 60 respondents being the smallest sample size allowed). The response propensity modeling approach allows data to be combined across occupations to form the appropriate adjustments for unit nonresponse at the occupation level.

The base establishment weights are adjusted for nonresponse using constrained logistic regression models that contain different combinations of the following variables:

- Industry division
- U.S. Census division
- establishment size
- headquarters/branch type
- number of occupations asked about in an establishment
- urban vs. rural location
- time zone
- ZIP code information from the 2000 U.S. Census
 - racial distribution
 - percentage of owner-occupied housing.

In addition, the employee weights are adjusted for nonresponse using a constrained logistic regression model developed using the same list of variables used for the establishment nonresponse adjustment, with the addition of occupation-specific indicator variables to the model. Adding occupation indicators to the model maintains the correct sum of weights for each occupation while also using data across occupations for the other variables in the model to improve the adjustment.

4. Establishment Nonresponse

Table A-1 in *Appendix A* displays the establishment eligibility and response rates for Analysis Cycle 1, 2, and 3 by step of data collection. The analysis population of establishments included each establishment that had at least one of its assigned occupations published in Analysis Cycles 1, 2, or 3, whether or not any of the occupations was eventually selected from the establishment. The response rates are presented separately by various variables to allow examination of the possibility of nonresponse bias. These variables were selected because they were available for both respondents and nonrespondents and were likely to be related to the primary outcome variables of the O*NET Program. Rates marked with an asterisk (*) are significantly different from the overall rates (where the overall rates are assumed to be fixed quantities).²

The following describes the columns and rows in *Table A-1*:

Columns:

- **Total Estab** is the total number of selected establishments at the Verification step.
- **Verification, Screening, Recruiting, and Sampling** refer to the four steps of data collection used in recruiting establishments. Rates were computed using only those establishments that responded at the previous step. For example, Screening rates reflect only establishments that responded at the Verification step. For the very first wave of data collection, Wave 1.1, there was no distinction between the Verification and Screening steps. These establishments were all considered eligible and responding at the Verification step in this analysis. **Final** rates are compounded rates across all steps of data collection.
- **Elig** is the percentage of establishments that are considered eligible. Establishments are considered survey-eligible if they are classified as (1) at the same street address or building, (2) in business (permanently or temporarily), (3) able to be located, and (4) not a duplicate. Establishments that have no employees in the list of occupations asked about during data collection are not considered survey-ineligible but rather as Sampling step respondents.
- **Resp** is the percentage of eligible establishments that are considered respondents; that is, they did not refuse to participate in the study.

Rows:

- **Census Division** is assigned using the address of the establishment. A total of 209 establishments from the analysis population had no address information because they went out of business between the time the initial sample frame was constructed and the onset of data collection. They were therefore declared ineligible at the Verification step. These establishments were assigned to the “Unknown” Census division, where the eligibility rate at the Verification step is 0%. Note that this also affects the Time Zone and Metropolitan Status rows.

² The tests were conditioned on the overall rates since the object was to determine any subgroups that differed from the observed overall rate.

- **Total Employees in Establishment** is the establishment total employment estimate on the sample frame. The category “Unknown” for total employees in an establishment is an actual frame classification.
- **SIC Division** is the Standard Industry Classification of the establishment.
- **Number of SOCs on Establishment Sampling List** is the number of occupations linked to an establishment’s sampling list. This may be viewed as a measure of the POC’s perceived level of burden.
- **Time Zone** and **Metropolitan Status** were assigned using the establishment’s ZIP code.

4.1 Comments on Establishment Final Unweighted Response Rates

The data in *Table A-1* reveal that the final unweighted³ response rate for establishments was 64.0%, and the final eligibility rate was 85.6%. The data also indicate that response rates were variable across the four data collection steps, with the lowest response rate occurring at the Recruiting step (76.6%) and the lowest eligibility rates occurring at the Verification (91.5%) and Screening (94.5%) steps. These results are intuitive because:

- It was not until the Recruiting step of data collection that the POC fully realized the burden involved in participation. Consequently, it was expected that most nonresponse would occur at this step.
- The first contact made to each establishment occurred at the Verification step. Because this is the step of data collection during which those establishments that have gone out of business become known, it was expected that the eligibility rate would be lower at this step. The slightly deflated eligibility rate observed between the Verification and Screening step is most likely due to the fact, as discussed above, that all Wave 1.1 establishments from the analysis population were considered to be eligible and responding at the Verification step. After combining both the Verification and Screening steps, the eligibility rate was 86.5%, which was considerably lower than the rate during the other two steps of data collection.

Using frame information, the respondents and nonrespondents can be compared across various attributes to approximate nonresponse bias. An estimate of the first component of nonresponse bias can be found in *Table A-1* under the column Final Response. As discussed above, low response rates are an indication of potential nonresponse bias. Treating the final unweighted response rate as a fixed quantity with no variance, the response rate for each level of a specific attribute was assessed against the overall value to determine if the difference is significant. Differences statistically significant at the 0.05 level are indicated with an asterisk (*). The results indicate the following:

- **Region.** It appears that establishments in the Mountain (68.0%) region had the highest significant final response rate, while the Middle Atlantic (59.5%) region had the lowest significant final response rate.

³ Unweighted rates were used because appropriate weights were not available for ineligible or nonresponding establishments.

- **Total number of employees.** Ignoring the Unknown category, there appears to be a decreasing trend in the final response rates as the size of the establishment increases. This suggests that the perceived burden of the POCs in smaller establishments may have been lower than the perceived burden of the POCs in larger establishments. In addition, in larger organizations, the decision to participate may not be at the discretion of the POC, but involve corporate approval. This is consistent with other literature, such as Willamack, Nichols, and Sudman (2002) and Tomaskovic-Dewey, Leiter, and Thompson (1994).
- **SIC division.** Comparing the different SIC divisions to the overall final response rate, Public Administration (77.8%) and Mining (73.6%) industries had the highest significant final response rates, while the Retail Trade (55.0%) industry had the lowest final response rate. Response rate patterns by industry are highly dependent on the occupations included in a particular collection of occupations. Thus, these findings would not necessarily apply to a different set of occupations in other analysis cycles.
- **Number of occupations.** At the Recruiting step, the response rate for establishments with one to five occupations on the sampling list (85.9%) was significantly higher than the overall response rate of 76.6%, indicating again that the POC may perceive a lower number of O*NET occupations as less of a burden. Interestingly, though, the establishments with one to five occupations listed had a significantly lower response rate at Verification. Overall, there is no discernible trend in the final response rates by number of occupations asked.
- **Metropolitan status.** Compared to the overall response rate, it appears that rural establishments (71.9%) had a final response rate significantly higher than the overall response rate, while urban establishments (62.4%) had a significantly lower final response rate.

4.2 Comparison of Establishment Respondents and Nonrespondents

Table A-2 shows a comparison of the distribution of respondents and nonrespondents across various establishment attributes. The column Difference in Percent (Respondents vs. Nonrespondents) reveals an estimate of the second component of nonresponse bias. As discussed above, a potential source of nonresponse bias occurs when this difference becomes large. An estimate of the nonresponse bias across an attribute (see equations 3.2 and 3.4) is shown in the last column, Difference in Percent (Respondents vs. Overall). Differences between respondents and overall marked with an asterisk are statistically different from each other at the 0.05 level. Large positive or negative values indicate potential evidence of nonresponse bias. While there are numerous statistically significant differences, the large sample sizes make it likely that very small differences will be statistically significant. In this situation, it is important to determine if the differences are of sufficient magnitude to be meaningful. For establishment nonresponse, the differences between respondents and overall do not appear to be meaningful. For instance:

- Approximately 65.1% of the attributes had an absolute bias⁴ of less than 1 percentage point.

⁴ Absolute value of the last column of *Table A-2*.

- Approximately 18.6% of the attributes had an absolute bias of at least 1 but less than 2 percentage points.
- Approximately 16.3% of the attributes had an absolute bias of at least 2 but less than 3 percentage points.

Another measure of potential nonresponse bias is the effect size as defined by Cohen (1988). In this case, the effect size is related to the chi-square test for comparing the equivalence of percentage distributions from respondents and overall for the variables listed in *Table A-2*. Cohen classified an effect size as “small” when it is about 0.10, as “medium” when it is about 0.30, and as “large” when it is about 0.50. For the variables in *Table A-2*, all of the effect sizes were small, with only one variable exceeding an effect size of 0.10 (0.13 for Total Employees in Establishment). The combination of small absolute biases and very small effect sizes indicate a low likelihood of bias due to establishment nonresponse.

5. Employee Nonresponse

Table B-1 in *Appendix B* displays the unweighted⁵ response rates for employees from Establishment method data collection for occupations published in Analysis Cycles 1, 2, or 3. The following describes the columns and rows in *Table B-1*:

Columns:

- **Sampled** is the total number of selected employees.
- **Response Rate** is the unweighted percentage of selected employees who responded by returning a completed domain questionnaire.

Rows:

In addition to the categories displayed in *Table A-1*, *Table B-1* also displays response rates by the following employee-level requirements:

- **Selected Employees in Establishment** is the number of employees who were selected from the establishment. Note that this value ranges from only 1 to 20. In Wave 1.1, the maximum number of employees to be selected from an establishment was 15, but beginning in Wave 1.2, it was decided to allow up to 20 employees to be selected from any single establishment per 12-month period.
- **Questionnaire Type** is the type of questionnaire that the employee was selected to complete (Skills, Work Activities, Work Context, or Knowledge).
- **Occupation Class** is derived from the first two digits of the O*NET SOC.

The response rates are presented separately by the various row variables to allow examination of the possibility of nonresponse bias. These variables were selected because they were available for both respondents and nonrespondents and likely to be related to the primary outcome variables of the O*NET Program.

5.1 Comments on Employee Response Rates

Employee nonresponse, similar to establishment nonresponse, is difficult to thoroughly characterize in the O*NET Data Collection Program because relatively little information is known about the nonrespondents (except for some descriptive frame characteristics). However, as with the establishment level, using information known about both responding and nonresponding employees, it is possible to determine indirectly if the nonrespondents are different from the respondents across variables that may be highly correlated with the survey data being collected. Thus, potential sources of nonresponse bias can be approximated at the employee level. An estimate of the first component of nonresponse bias can be found in *Table B-1* under the column Response Rate. As discussed in *Section 3*, low response rates are a potential indication of nonresponse bias. Treating the final unweighted response rate as a fixed quantity with no variance,⁶ the response rate for each level of a specific covariate was assessed

⁵ Unweighted rates were used because appropriate weights were not available for nonresponding employees.

⁶ The tests were conditioned on the overall rates since the object was to determine any subgroups that differed from the observed overall rate.

against the overall value to determine if the difference was significant. Differences statistically significant at the 0.05 level are indicated with an asterisk (*). The unweighted results indicate the following:

- **Region.** Employees in the West North Central (66.9%) and East North Central (66.4%) divisions had the highest significant response rates, and employees in the Pacific (58.9%) division had the lowest significant response rates.
- **Total number of employees.** There appears to be a decreasing trend in the employee response rates as the size of the establishment increases. However, this trend is not as prominent as that observed at the establishment level.
- **Number of selected employees.** Much variation exists in the response rate across the number of selected employees. However, it appears that the response rates are higher when the selected number of employees is five or fewer than when the selected number of employees exceeds five.
- **Questionnaire type.** The response rates do not appear to vary greatly across questionnaire type, with the highest response rate (65.5%) associated with the Work Context questionnaire and the lowest response rate (61.4%) associated with the Work Activities questionnaire, both of which are statistically different from the overall rate.
- **SIC division.** Agriculture, Forestry, and Fishing (71.6%) and Public Administration (68.7%) had the highest significant response rates when compared to the overall response rate, while Construction (56.0%) and Retail Trade (56.1%) had the lowest significant response rates.
- **Occupation classes.** Compared to the overall response rate, Education, Training, and Library Occupations (78.3%), Life, Physical, and Social Science Occupations (69.3%) and Management Occupations (69.0) had the highest significant response rates, while Food Preparation and Serving Related Occupations (51.6%) and Construction and Extraction Occupations (55.0%) had the lowest significant response rates.
- **Number of occupations.** There is no clear pattern in the employee response rate by the number of occupations on the establishment sampling list.
- **Metropolitan status.** The findings at the employee level were similar to the findings at the establishment level. That is, the overall response rate for employees from rural areas was significantly higher than those from urban areas.

5.2 Comparison of Employee Respondents and Nonrespondents

Table B-2 presents a comparison of the distribution of respondents and nonrespondents across various employee attributes. The column Difference in Percent (Respondents vs. Nonrespondents) reveals an estimate of the second component of nonresponse bias. As discussed above, a potential source of nonresponse bias occurs when this difference becomes large. The column Difference in Percent (Respondents vs. Overall) shows an estimate of the nonresponse bias across an attribute (see equations 3.2 and 3.4). Differences between respondents and overall marked with an asterisk are statistically different from each other at the 0.05 level. Large positive or negative values indicate potential evidence of nonresponse bias. While there are numerous statistically significant differences, the large sample sizes make it likely that very small

differences can be statistically detected. In this situation, it is important to determine if the differences are of sufficient magnitudes to be meaningful. For employee nonresponse, the differences between respondents and overall do not appear to be meaningful. For instance:

- Approximately 88.8% of the attributes had an absolute bias⁷ of less than 1 percentage point.
- Approximately 11.2% of the attributes had an absolute bias of at least 1 but less than 2 percentage points.

Another measure of the possibility for nonresponse bias is the effect size as defined by Cohen (1988). In this case, the effect size is related to the chi-square test for comparing the equivalence of percentage distributions from respondents and overall for the variables listed in **Table B-2**. Cohen classified an effect size as “small” when it is about 0.10, as “medium” when it is about 0.30, and as “large” when it is about 0.50. For the variables in **Table B-2**, all of the effect sizes were small (less than 0.10).

The combination of small absolute biases and very small effect sizes indicate a low likelihood of bias due to employee nonresponse.

⁷ Absolute value of the last column of **Table B-2**.

6. Item Nonresponse

Tables C-1 through C-8 in Appendix C display unweighted item response rates by item, item type, and occupation. These tables include questionnaire data from employee respondents in the 287 occupations published in Analysis Cycles 1, 2, and 3 completed using the Establishment method. Only items from those questionnaires classified as “complete” were evaluated. Cases with incomplete questionnaires were included as employee nonrespondents in *Section 5*.

6.1 Comments on Item Response Rates

Item nonresponse is analogous to partial information patterns in which some variables are observed and some are missing. Despite the fact that partial information is present, item nonresponse can still create biased parameter estimation if the missing values are systematically related to the outcome (e.g., wealthy respondents tend to leave an income question missing). The results indicate the following:

- **Skills, Work Activities, and Work Context.** The data in *Tables C-1 through C-4* suggest that for the Skills, Work Activities, and Work Context questionnaires, there is little item nonresponse with respect to a single item on each questionnaire. The minimum response rate for any specific item is 94.7% for the Skills questionnaire item 22 (Level), 95.3% for the Work Activities questionnaire item 40 (Level), 97.7% for item 49 of the Work Context questionnaire, and 92.1% for the Knowledge questionnaire item E08 (Level). In addition, as seen in *Table C-7*, item nonresponse is slightly more prevalent for Level items than Importance items, regardless of questionnaire type.
- **Occupation-specific tasks.** It appears from *Table C-5* that item nonresponse may be potentially more serious for certain Frequency and Importance items. However, it should be noted that the eligible sample size is small for these Frequency and Importance items because a responding employee is not required to respond to the corresponding Frequency and Importance item if he/she does not consider a task to be relevant. Most of the Frequency and Importance items with a low response rate are suppressed from publication because they were also found to be not relevant to the occupation since too few respondents rated the task as relevant. Another explanation of the low response rates on these items involves those employees in Wave 1.1 who returned a domain questionnaire but failed to return a Task questionnaire. In these cases, all Task items for these employees were classified as “item nonresponse.” This latter situation cannot occur after Wave 1.1 due to a change in data collection methodology.
- **Background questionnaire.** In *Table C-6*, item response rates appear to be nearly constant and high (over 94%), with the exception of item 4. This item elicits information from the respondent about working in a family business (81.8%).
- **Item type.** The response rates by item type in *Table C-7* are all over 95%.
- **Occupation.** Item response rates are provided in *Table C-8* for all occupations completed in the first three analysis cycles. The overall item response rate is 97.8%, with the smallest response rate, 93.9%, coming from Home Health Aides (SOC 31-1011.00), and the largest, 99.6%, coming from Mining and Geological Engineers, Including Mining Safety

Engineers (SOC 17-2151.00). The extremely high item response rates indicate a low likelihood of bias due to item nonresponse.

7. Conclusion

Unit and item nonresponse can lead to biased inferences if the nonresponse rates are high and respondents and nonrespondents differ relative to the requirements of interest. An examination of both establishment and employee response rates found that nonresponse patterns are somewhat related to essentially all variables considered in the analyses. However, when examining the distribution of respondents and nonrespondents across various frame attributes, it was found that the overall potential for nonresponse bias at both the establishment and employee levels was negligible. For both establishments and employees, both the absolute size of any potential bias and the effect size were found to be small for all variables considered. Because nonresponse patterns for both establishments and employees are related to the substantive variables measured in the study, using these variables for nonresponse adjustments to the analysis weights should be effective at reducing the minimal effects, if any, due to nonresponse bias in the analysis.

At the item level, it was found that different questionnaire types and questions exhibited varying response rates, and in most cases the response rates were extremely high. This finding coincides with the findings at the establishment and employee levels—that is, the potential for significant nonresponse bias due to item nonresponse is negligible.

Appendix C: Item Response Tables

Table C-1. Ten Lowest Item Response Rates, Skills Questionnaire

Item	Item Description	Sampled	Response Rate
A22-Level	Writing computer programs for various purposes.	3,202	94.7
A30-Level	Identifying measures or indicators of system performance and the actions needed to improve or correct performance, relative to the goals of the system.	6,305	96.6
A19-Level	Generating or adapting equipment and technology to serve user needs.	5,984	96.9
A28-Level	Repairing machines or systems using the needed tools.	5,169	97.0
A21-Level	Installing equipment, machines, wiring, or programs to meet specifications.	4,937	97.2
A24-Level	Watching gauges, dials, or other indicators to make sure a machine is working properly.	5,655	97.2
A29-Level	Determining how a system should work and how changes in conditions, operations, and the environment will affect outcomes.	6,095	97.3
A34-Level	Obtaining and seeing to the appropriate use of equipment, facilities, and materials needed to do certain work.	6,331	97.3
A33-Level	Determining how money will be spent to get the work done, and accounting for these expenditures.	5,596	97.3
A26-Level	Performing routine maintenance on equipment and determining when and what kind of maintenance is needed.	6,148	97.4

Table C-2. Ten Lowest Item Response Rates, Work Activities Questionnaire

Item	Item Description	Sampled	Response Rate
B40-Level	Recruiting, interviewing, selecting, hiring, and promoting employees in an organization.	4,266	95.3
B21-Level	Providing documentation, detailed instructions, drawings, or specifications to tell others about how devices, parts, equipment, or structures are to be fabricated, constructed, assembled, modified, maintained, or used.	3,650	95.4
B22-Level	Servicing, repairing, adjusting, and testing machines, devices, moving parts, and equipment that operate primarily on the basis of mechanical (not electronic) principles.	3,903	95.5
B23-Level	Servicing, repairing, calibrating, regulating, fine-tuning, or testing machines, devices, and equipment that operate primarily on the basis of electrical or electronic (not mechanical) principles.	4,012	95.8
B05-Level	Estimating sizes, distances, and quantities; or determining time, costs, resources, or materials needed to perform a work activity.	7,435	96.3
B41-Level	Monitoring and controlling resources and overseeing the spending of money.	5,999	96.4
B02-Level	Identifying information by categorizing, estimating, recognizing differences or similarities, and detecting changes in circumstances or events.	8,960	96.4
B06-Level	Assessing the value, importance, or quality of things or people.	8,183	96.5
B13-Level	Establishing long-range objectives and specifying the strategies and actions to achieve them.	7,427	96.6
B32-Level	Performing for people or dealing directly with the public. This includes serving customers in restaurants and stores, and receiving clients or guests.	7,313	96.6

Table C-3. Ten Lowest Item Response Rates, Work Context Questionnaire

Item	Item Description	Sampled	Response Rate
D49	How automated is the job?	10,229	97.7
D45	How serious would the result usually be if the worker made a mistake that was not readily correctable?	10,229	98.1
D55	How important is it to this job that the pace is determined by the speed of equipment or machinery? (This does not refer to keeping busy at all times on this job.)	10,229	98.7
D47	How frequently is the worker required to make decisions that affect other people, the financial resources, and/or the image and reputation of the organization?	10,229	98.7
D53	To what extent does this job require the worker to compete or to be aware of competitive pressures?	10,229	98.7
D51	How important is repeating the same physical activities (e.g., key entry) or mental activities (e.g., checking entries in a ledger) over and over, without stopping, to performing this job?	10,229	98.8
D12	How often are there conflict situations the employee has to face in this job?	10,229	99.0
D39	How much does this job require keeping or regaining your balance?	10,229	99.0
D42	How much does this job require making repetitive motions?	10,229	99.0
D09	How important is it to coordinate or lead others in accomplishing work activities in this job?	10,229	99.0

Table C-4. Ten Lowest Item Response Rates, Knowledge Questionnaire

Item	Item Description	Sampled	Response Rate
E08-Level	Knowledge of techniques and equipment for planting, growing, and harvesting food products (both plant and animal) for consumption, including storage/handling techniques.	1,635	92.1
E38	Length of apprenticeship required to perform the job?	9,823	92.3
E26-Level	Knowledge of the theory and techniques required to compose, produce, and perform works of music, dance, visual arts, drama, and sculpture.	1,735	93.5
E34	The level of education required to perform a job.	9,823	95.7
E27-Level	Knowledge of historical events and their causes, indicators, and effects on civilizations and cultures.	2,621	95.9
E12-Level	Knowledge of materials, methods, and the tools involved in the construction or repair of houses, buildings, or other structures such as highways and roads.	2,877	96.4
E17-Level	Knowledge of plant and animal organisms, their tissues, cells, functions, interdependencies, and interactions with each other and the environment.	2,922	96.5
E03-Level	Knowledge of economic and accounting principles and practices, the financial markets, banking and the analysis and reporting of financial data.	5,446	96.7
E07-Level	Knowledge of raw materials, production processes, quality control, costs, and other techniques for maximizing the effective manufacture and distribution of goods.	5,124	96.9
E28-Level	Knowledge of different philosophical systems and religions. This includes their basic principles, values, ethics, ways of thinking, customs, practices, and their impact on human culture.	3,598	97.0

Table C-5. Ten Lowest Item Response Rates, Task Questionnaire

Item	Item Description	Sampled	Response Rate
29-2011.00, Medical and Clinical Laboratory Technologists: T17-Importance	Prepare vaccines and biological serums for disease prevention.	6	0.0
29-2011.00, Medical and Clinical Laboratory Technologists: T17-Frequency	Prepare vaccines and biological serums for disease prevention.	6	0.0
33-9092.00, Lifeguards, Ski Patrol, and Other Recreational Protective Service Workers: T9-Frequency	Drive a four-wheel drive vehicle equipped for major emergencies such as beached boats or cliff accidents.	2	0.0
29-2011.00, Medical and Clinical Laboratory Technologists: T14-Importance	Cut images of chromosomes from photograph and identify and arrange them in numbered pairs on karyotype chart, using standard practices.	6	16.7
29-2011.00, Medical and Clinical Laboratory Technologists: T14-Frequency	Cut images of chromosomes from photograph and identify and arrange them in numbered pairs on karyotype chart, using standard practices.	6	16.7
53-7111.00, Shuttle Car Operators: T10-Frequency	Place planks between coke ovens and tops of railroad cars in order to provide paths for wheelbarrows.	9	22.2
19-4092.00, Forensic Science Technicians: T1-Frequency	Test race horses and racing dogs for substances that may affect their performances.	4	25.0
43-4121.00, Library Assistants, Clerical: T22-Frequency	Drive bookmobiles to specified off-site locations following library service schedules, and to garages for preventive maintenance and repairs.	11	27.3
29-2011.00, Medical and Clinical Laboratory Technologists: T9-Importance	Prepare slide of cell culture to identify chromosomes, view and photograph slide under photo-microscope, and print picture.	7	28.6
29-2011.00, Medical and Clinical Laboratory Technologists: T9-Frequency	Prepare slide of cell culture to identify chromosomes, view and photograph slide under photo-microscope, and print picture.	7	28.6
53-3041.00, Taxi Drivers and Chauffeurs: T12-Frequency	Drive automobiles in order to escort vehicles carrying wide loads.	7	28.6

Table C-6. Response Rates, Background Questionnaire

Item	Item Description	Sampled	Response Rate
2	How long at job?	39,671	99.5
3	Employment sector	39,671	94.1
4	Family business*	39,671	81.8
5	Age group	39,671	96.8
6	Gender	39,671	98.9
7	Ethnicity	39,671	96.7
8	Race	39,671	94.7
9A	Blindness, deafness, or other severe vision or hearing impairment	39,671	98.0
9B	A condition that substantially limits one or more basic physical activities such as walking, climbing stairs, reaching, lifting, or carrying	39,671	98.0
10A	Difficulty learning, remembering, or concentrating	39,671	95.1
10B	Difficulty bathing, or getting around inside the home	39,671	95.1
10C	Going outside the home alone to shop or visit the doctor's office	39,671	95.0
10D	Working at a job or business	39,671	95.0
11	Education level	39,671	96.6

*Note: Item 4, Family Business, was edited differently in analysis cycle 1 than in later Analysis Cycles. The number sampled in Analysis Cycle 1 was 5,150 with response rate 93.7. The total number sampled in Analysis Cycles 2 and 3 was 34,521 with response rate 80.0.

Table C-7. Item Response Rates by Item Type

Item Type	Questions	Response Rate
TOTAL	5,026,182	97.8
